

- Geometric outline:
 - Base @ cervix
 - triangular
 - apex @ incisal ridge

Root: Cone shaped / centralized / blunt

• Contact areas

- centralized labio-lingually
- incisal third near the mesio-incisal angle (inciso-cervically)

labial outline: convex at cervical third, slightly convex or flat on middle and incisal third

Mesial

- cervical line: curves incisally to a certain degree
- lingual outline

→ convex at cervical third Cingulum

→ Concave in the middle $\frac{1}{3}$ lingual Fossa

→ slightly convex incisal ridge

- Geometric outline :
Similar 2 mesial

- Outline form Similar 2 mesial

BUT

Root : convex w/ no depressions

Curvature of cervical line :
less distal than mesial.

Contact area : centralized ←
but is located more cervical

→ Crown is thicker towards
incisal third

Distal

outline : ↗ labial outline forms the base
↘ apex : lingually C lingual convergence

- Geometric outline:  apex: lingually C lingual convergence

labial outline relatively flat & broad
compared 2 lingual surface
Crown width $\longleftrightarrow$ is greater
than thickness $\downarrow$

Incisal

incisal ridge: centrally situated in $\leftarrow$
relation 2 the thickness

lingual fossa: is seen as a broad
concavity bet

• Geometric outline Δ :
w/ Shortest of uneven sides located
cervically

anatomy:

A) Elevations:

- Crown smoothly convex w/ maximum convexity @ cervical third
- mamelons in newly erupted teeth

B) Depressions: 2 dev grooves: 3 bbs

Contact area: more cervically @ junction of middle & incisal 1/3

Distoincisor: rounded angle

Roots:

- Single rooted / cone shaped / blunt centralized apex

extracted by rotational movement

Cervical outline: convex rootward

mesial outline: slightly convex

Contact area: @ maximum convexity in the incisal third

mesioincisal angle: sharp & nearly forms right angle

← near the angle

Labial

incisal outline:
- 3 mamelons that disappear.

• Geometric outline: similar to labial

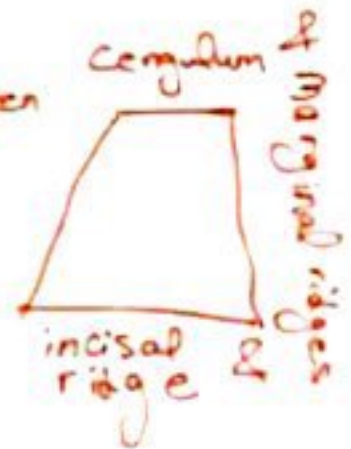

Lingual

roots: narrower than labial due to lingual convergence

- Surface anatomy
- cingulum: smooth large convexity in cervical third
- mesial & distal marginal ridges: extend from cingulum to incisal ridge

lingual fossa + LARGE concavity lies between incisal ridge

Crown: converges lingually

Why? to accommodate to the u shaped dental arch which have longer face facially than lingually
